Congenital Clasped Thumb

وکارش 8 مورد آن در ظرف مدت سه سال از بخش اورتوپدی مجتمع بیمارستانی امام خمینی

دکتر محمود فرمان استادیار گروه جراحی ارتودنسی دانشگاه علوم پزشکی تهران در بیمارستان امام خمینی

SUMMARY

This deformity is often referred to as the thumb-clutched hand, but a better term is the congenital clasped thumb.

The congenital clasped thumb is associated with several well-defined syndromes, although it may also present as an isolated abnormality. Weckesser, Reac, and Heiple called it a syndrome and divided the syndrome in to four groups. In Group I, the thumb is deficient in extension only. In Group II, flexion contractur combine with deficient extension. In Group III, the thumb is hypoplastic, and tendons and muscles are deficient. Group IV consists of the few remaining cases that so not fit into the first three groups. Group I cases are found three times as frequently as Group II Cases, while Group III and IV cases are five times less frequent than Group II cases.

The congenital clasped thumb is twice as common in males as in females and is nearly always bilateral. During the early weeks of life, an infant frequently clutches the thumb and releases it intermittently for spontaneous motion. However, by the third or fourth month of life, the normal child ceases to clasp his thumb under his fingers. If the clasping persists and normal independent action of the thumb does not develop, the syndrome of congenital clasped thumb is present.

خلاصه

یک دنیمی مادرزادی Congenital Clasped Thumb

شست است که در آن شست از محل مفصل مباکره‌البیین دچار فکشن شده و نیز می‌کاریب اول ادکلن پیانا کرد است. این دنیمی مادرزادی، همچنین وجود بالاتس بین...
