دکتر علی‌اصفهانی

There is no doubt that Smegma, a non-cornified granular cells with epithelial structure, is a carcinogen material. We have heavy concentration of smegma in childhood, particularly in early days of life.

In Persia circumcision is done usually when the child is 3-5 years old and sometimes in the period before the puberty, 10-14 years of age. This, we believe, could well be the account for a rather high incidence of penile carcinoma among Moslems population in Persia (at least in Tehran Region).
